HERESY CHANGES

The woofer system in our HERESY loudspeaker has undergone extended research and development over the past several years. Efficiency has improved to the point that the overall response has developed a broad "hump" centered about 100 Hertz. Although this hump is not usually objectionable, particularly with current popular music, we feel that it is time to "flatten" the response of the HERESY by raising the mid-range and tweeter levels by 3 dB each. We find the balance more satisfying, and the system less intolerant of the use of "loudness" and "tone" controls.

These changes will be effected about July 1, 1974, and will start with serial number 11M000. The Architect's and Engineer's specification sheets will reflect the specification changes with the next printing. The cross-over network incorporating the changes will be identified as Type "D".

HERESYS from about 5K718 may be updated by changing the network from Type "C" to Type "D", as shown below:

The mark of integrity in loudspeakers!

Richard R. Moore
Audio Engineer
